Bypassing Antivirus

With Understanding Comes Ease

Jeff McJunkin, Founder
Rogue Valley Information Security

Introduction and Agenda

- AV's main approaches to detecting and blocking malware
- Fundamental limitations of the above
- Bypassing AV -- Different Approaches
- Live Demo
- Further discussions
- Q&A

Antivirus / Antimalware / EDR's tools

1. Static detections - searching each EXE/DLL on load for bad strings/patterns
2. Hooking runtime API calls and searching for bad strings / patterns
   - Anti-Malware Scanning Interface (AMSI)
     - Otherwise, all PowerShell / JavaScript, etc only has static detections
   - Userland hooks
   - Kernel-level hooks (Not used for modern operating systems due to PatchGuard, but replaced by mini-filter drivers instead)
   - This approach is more prone to false positives and has fewer signatures
3. Dynamic detection (behavioral analytics during brief emulation)
   - This approach is also more prone to false positives, and has fewer signatures

All of the techniques result in a yes/no decision using "badness" scores

Some strings (such as "Copyright Benjamin Delpy" or "Invoke-Mimikatz") are suspicious, whereas others (such as "Copyright Microsoft 2020") are not.

"Next-Gen" Antivirus

But what about machine learning? What about artificial intelligence?

AI is only as smart as it needs to be (finding bad strings)

Researchers Easily Trick Cylance's AI-Based Antivirus Into Thinking Malware Is 'Goodware'

By taking strings from an online gaming program and appending them to malicious files, researchers were able to trick Cylance's AI-based antivirus engine into thinking programs like WannaCry and other malware are benign.
AMSI

- The Antimalware Scan Interface allows AV vendors to "see" PowerShell, JavaScript, VBScript, Office macros, and a few other scripting formats, after de-obfuscation and before execution
  - AV then gets to make a yes/no decision
- Not all AV vendors support AMSI (introduced in 2015)
- Symantec didn't support it until June 15, 2020 with SEP 14.3

Symantec ™ Endpoint Protection 14.3 Release Notes

This section describes the new features for the 14.3 release.

Protection Features

- Third-party application developers can protect their customers from dynamic script-based malware and from non-traditional avenues of cyberattack. The third-party application calls the Windows AMSI interface to request a scan of user-provided script, which is routed to the Symantec Endpoint Protection client. The client responds with a verdict to indicate on whether or not the script behavior is malicious. If the behavior is not malicious, then the script execution proceeds. If the script's behavior is malicious, the application does not run it. On the client, the Detection Results dialog box displays a status of "Access Denied." Examples of third-party scripts include Windows PowerShell, JavaScript, and VBScript. Auto-Protect must be enabled. This functionality works for Windows 10 and later computers.

How the Antimalware Scan Interface (AMSI) helps you defend against malware
Antimalware Scan Interface (AMSI)

Which Vendors Support AMSI?

https://github.com/subat0mik/whoamsi

My hot take: if your AV/EDR vendor doesn't support AMSI, they have no business in this industry, and don't deserve your money.

Fundamental Limitations of AV

- AV isn't tracking everything, for performance reasons
  - Each API call interception adds latency, and there are strong financial incentives to avoid perceptibly slowing down computers due to AV
    - Emulation maximum time varies, but I've never seen it over 0.25 seconds (@taviso mentioned a "million instructions")
  - AV intercepts far more than just running EXE files from disk
    - Examples: Loading additional DLL's, writing to other process's memory, creating new threads, extracting compressed content, checking for debuggers, and more
- AV companies have a strong financial incentive to minimize false positives, which means A) accepting false negatives and B) brittle signatures

With AV, bots are fighting bots. Unfortunately, attackers can study AV's behavior, and they take the last move.

Rock 'Em, Sock 'Em

Right: https://winternl.com/fuzzing-the-windows-api-for-av-evasion/

github.com/NavyTitanium/Fake-Sandbox-Artifacts

README.md

Fake Sandbox Artifacts (FSA)

Inspired from the PowerShell script Fake Sandbox Processes (FSP), this script allows you to create various artifacts on a bare-metal Windows computer in an attempt to trick malwares that looks for VM or analysis tools.

The names of the artifacts to be created are separated in text files in the different folders to allow easy modification.

Background

It is estimated that 15-20% [13] of malwares are aware of virtual machine environment and will either abort execution or change its behavior upon detection. Also, *fingerprinting tactic is still the dominant approach to evade sandboxes.* [15]

## Fuzzing the Windows API for AV Evasion

July 7, 2020

What is emulation?

Malware Detection Systems (MDSs) use a technique called emulation as perhaps their most effective weapon against novel malware threats. Emulation does not rely on the static structure or *signature* of a file, but instead, executes the suspicious file for you. Of course, the MDS will not run the file on your computer, but rather in some artificial environment that *emulates* a real operating system. Based on heuristic analysis of the execution, the MDS will conclude whether the behavior of the file was benign or malicious and will issue a detection accordingly. MDS emulation environments have come a long way in the past decade, but are still plagued by an axiomatic fallacy ripe for exploitation.

Relationship Between False Positives and False Negatives

Commonly discussed in testing theory, but terminology is often used elsewhere (categorization theory, AV/EDR, etc)
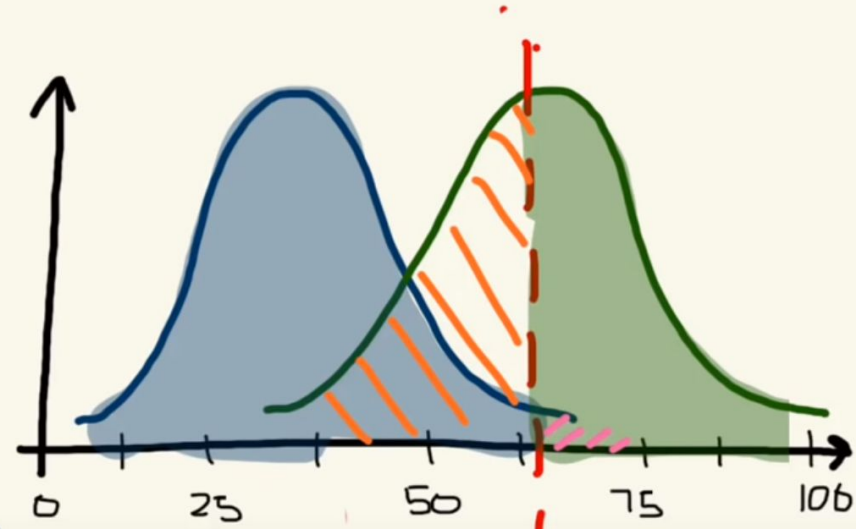

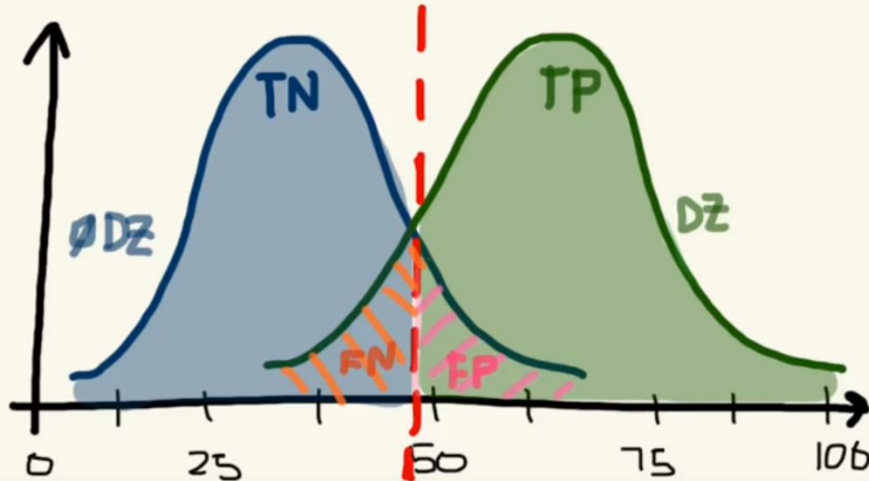

Relationship Between False Positives and False Negatives

False Positive: Marking a benign binary (such as Notepad.exe) as malicious

False Negative: Marking a malicious binary (such as Mimikatz.exe) as safe

False Positives cost more than False Negatives, in PR and market share

Brittle Signatures, Demonstrated

Andrew Healey
@healeyio

Haha. My SSID triggers Microsoft Defender @WindowsATP because Invoke-Mimikatz.ps1.

Actions ⌄

"Copyright Benjamin Delpy": unlikely to have false positives, but all sorts of legitimate software accesses LSASS as well.

DEMO:
Bypassing Static Signatures To Use Mimikatz

Mick Douglas
@bettersafetynet

Replying to @jeffmcjunkin and @taviso

If you ever want to realize how... thin... the defenses are that we rely on. DefenderCheck.

I am deeply worried about the detection tools we rely on... they are nowhere near what we *think* they are.

Disadvantages for Security Professionals

Security professionals tend to…

1. Talk about their bypass methods
   - As shown on the prior slide, this tends to result in quickly-updated vendor signatures
2. Use public toolsets (Metasploit, Empire, Covenant, Veil-Evasion)
   - AV vendors spend a disproportionate amount of time making signatures for public tools
   - Security professionals often make their own non-public toolset to take advantage of this, to good effect (BHIS included)
3. Upload to VirusTotal to test their payloads
   - …which results in every single AV vendor getting a copy of the payload

Methods of Bypassing Antivirus

1. **Use non-malicious software in malicious ways (preferred)**
    - Instead of Metasploit's psexec implementation, use PsExec.exe from Microsoft
    - Instead of Mimikatz.exe, dump LSASS memory with Task Manager and extract passwords elsewhere
    - Instead of hashdump, save out registry hives and extract hashes elsewhere
    - Instead of meterpreter (at first), use Remote Desktop, mRemote-NG, TeamViewer, etc.

In general, avoid fair fights (both against AV and in life)

Example of #1 Approach

bleepingcomputer.com/news/security/fxmsp-chat-logs-reveal-the-hacked-antivirus-vendors-avs-respond/

Fxmsp Chat Logs Reveal the Hacked Antivirus Vendors, AVs Respond

(1:20:52) **uwerty5411@exploit.im**: система не палит, потому что тимка и анидеск лигитимное, и админы сети там тоже пользуются ими по этому нет подозрений
(1:21:22) **uwerty5411@exploit.im**: там все в разных местах и объемы большие
(1:21:49) **uwerty5411@exploit.im**: при скачивании будет долго там общее 1000 терабайт
(1:22:23) **uwerty5411@exploit.im**: плюс при выкачивании всего и сразу займет месяцы, очень рискованно выгружать сразу все

Here's the translation of the chat log:

```
Fxmsp: the [TrendMicro] access is to a local corporate network
Fxmsp: you have unfettered access in their network environment
Fxmsp: no, you can only move laterally via credentialed net shares or RDP
Fxmsp: the access sold is via TeamViewer or AnyDesk remote software
Fxmsp: their network defense does not see us b/c teamViewer and AnyDesk are
legit software, and admins also use it there. That is why no questions.
```

Methods of Bypassing Antivirus

2. Make an unfair fight:
   - Run inside PowerShell version 2, which doesn't support AMSI, even on Windows 10
   - Use API calls that aren't intercepted
   - "Unhook" API calls so antivirus doesn't have any visibility
     - Read https://github.com/NtRaiseHardError/Antimalware-Research/ for more on this!
   - Detect AV's sandboxed environments and run differently there:
     - https://github.com/David-Reguera-Garcia-Dreg/anticuckoo
     - https://winternl.com/fuzzing-the-windows-api-for-av-evasion/
   - Encrypt the payload and only decrypt at runtime (Hyperion, bypasses static signatures and emulation)
   - Add extra strings (from legitimate software) to increase the "goodness" score
   - Add extra data to go above certain thresholds

```
#                                                                      #
# DESCRIPTION                                                          #
# Hyperion is a runtime encrypter for 32/64 bit portable executables. It is a #
# reference implementation and bases on the paper "Hyperion: Implementation #
# of a PE-Crypter". The paper describes the implementation details which  #
# aren't in the scope of this readme file.                             #
# The crypter is a C project and can be compiled with the corresponding  #
# makefile (tested with Mingw and Visual Studio). Afterwards it is started  #
# via the command line and encrypts an input executable with AES-128. The  #
# encrypted file decrypts itself on startup (bruteforcing the AES key which  #
# may take a few seconds) and generates a log file for debug purpose.    #
```

3. If necessary: Stack the odds in your favor before a fair fight through the following methodology:

- Install the AV in an isolated virtual machine
  - (which doesn't report to vendor or client)
- Update AV signatures
- Take a snapshot
- Disconnect network adapter
- Introduce malware
- If discovered, modify and repeat as necessary
- Revert to snapshot (no matter what)

Application Control

- AV (stopping malicious software while allowing legitimate software) has a literally impossible job
    - There are infinite ways to accomplish a given task, whether it's "Hello World", meterpreter, Mimikatz, or ransomware
    - Determining whether software is "malicious" is definitely a harder problem than the Halting Problem, which was proven impossible to solve in 1936
- Instead, focus on application control, only allowing known-good software, such as Microsoft-signed binaries, known vendor software, and internally-developed applications

Halting problem

From Wikipedia, the free encyclopedia

In computability theory, the **halting problem** is the problem of determining, from a description of an arbitrary computer program and an input, whether the program will finish running, or continue to run forever. Alan Turing proved in 1936 that a general algorithm to solve the halting problem for all possible program-input pairs cannot exist. For any program

Application Control: Bypasses

- Allowing only signed Microsoft binaries isn't 100% effective
- Some signed binaries allow arbitrary code execution directly
  - Some refer to these as "LOLBINS" for Living Off the Land BINaries
  - Example: MSBuild.exe allows compiling applications and running arbitrary C# code
  - Many are documented at https://lolbas-project.github.io/ (Living Off the Land Binaries And Scripts)

Verified AppLocker bypasses for Default rules

This list contains all the bypasses that has been verified to bypass AppLocker default rules.

Installutil.exe
Msbuild.exe
Mshta.exe
Presentationhost.exe
Regasm.exe
Regsvcs.exe

A Better Approach with AV

1. Rely on detection in depth and rapid response, not solely preventive controls
2. Plug AV alerts into monitoring feeds for Security Operations Centers
   ○ Anecdote here about DC
3. React quickly to AV alerts <u>including root cause analysis</u>
4. Don't pick products based on the Gartner Magic Quadrant, but factor it into your own evaluations
   ○ Anecdotally, Defender is the toughest to bypass
5. Spend effort on application control as well, with EDR and AV as additional layers

Figure 1. Magic Quadrant for Endpoint Protection Platforms

CHALLENGERS | LEADERS

- Microsoft
- CrowdStrike
- Symantec
- Trend Micro
- Sophos
- ESET
- McAfee
- Kaspersky
- BlackBerry Cylance
- Bitdefender
- FireEye
- Cisco
- Carbon Black
- F-Secure
- Panda Security
- SentinelOne
- Palo Alto Networks
- Check Point Software Technologies
- Fortinet
- Malwarebytes

ABILITY TO EXECUTE

NICHE PLAYERS | VISIONARIES

COMPLETENESS OF VISION — As of August 2019 © Gartner, Inc

Source: Gartner (August 2019)

AV's own attack surface

Some attributes of AV:

- Highly privileged
- Often not sandboxed
- Evaluates untrusted inputs and code
- Often not logged
- Sometimes has poor software protections

How to Compromise the Enterprise Endpoint

Posted by Tavis Ormandy.

Symantec is a popular vendor in the enterprise security market, their flagship product is Symantec Endpoint Protection. They sell various products using the same core engine in several markets, including a consumer version under the Norton brand.

Today we're publishing details of multiple critical vulnerabilities that we discovered, including many wormable remote code execution flaws.

These vulnerabilities are as bad as it gets. They don't require any user interaction, they affect the default configuration, and the software runs at the highest privilege levels possible. In certain cases on Windows, vulnerable code is even loaded into the kernel, resulting in remote kernel memory corruption.

```

Authenticode      : "Present"
.NET              : "NotPresent"
```

Closing Statement

To prevent successful breaches, defenders need to detect and respond to attackers before they accomplish their goal. Therefore, defenders have two goals:

1. Lowering the time to detect and respond to an attacker
2. Making it take longer for an attacker to accomplish their goal

Prevention is ideal, but it's impossible to prevent 100% of incidents. Therefore, focus on minimizing, detecting, and accelerating response to incidents.
